# The value of blue-space recreation and water quality across Europe: A contingent behaviour study (Börger et al. 2021) 

Supplementary Materials

## Content

A. Data
B. Construction of travel cost variable
C. Computation of confidence intervals
D. Alternative regression analysis as robustness check

## A. Data

## A.1. Survey data

The dataset was collected in four waves between June 2017 and April 2018, resulting in a sample of $N=$ 18,838 respondents across 18 countries or territories (Bulgaria, California/USA, Canada, Czech Republic, Estonia, Finland, France, Germany, Greece, Hong Kong, Ireland, Italy, Netherlands, Portugal, Queensland/Australia, Spain, Sweden, United Kingdom). The analysis only uses data from 14 EU Member States (i.e. cases from California, Canada, Hong Kong and Queensland were discarded). Further exclusion criteria are detailed in Section A.3.

Respondents were asked about their visits to blue- and greenspace sites over a period of four weeks. Types of green space listed in the questionnaire included local parks, large parks, community gardens, playgrounds, cemeteries, botanical gardens or zoos, woodlands, farmland, meadows, mountains, moorland and country parks. Types of blue space listed in the questionnaire were lakes, urban rivers, rural rivers, waterfalls, ponds, wetlands, swimming pools or spas, fountains, ice rinks, esplanades or promenades, harbours, beaches, rocky shores, cliffs, lagoons or the open sea. They were then asked to give more information about trips to the last blue-space site they had visited. So whilst respondents determined themselves which site to report on, an element of random selection of site was introduced by asking them about their most recent site. This is to prevent all respondents to state visit information regarding their most favourite or most frequently visited site.

The present study differs from previous applications of the travel cost and contingent behaviour methods in that it assesses the value of recreation at different blue space sites yet without identifying each site. Instead, sites can be characterised using a number of criteria such that the recreational values can be broken down according to these categories. The good to be valued in this study is two-fold: (1) recreational
visits to blue space sites and (2) changes to this recreational value as a reaction to changes in water quality at such sites.

Although the full dataset includes a share of respondents who did not make any trip to a blue space site in the past four weeks and therefore report a zero for the trip frequency variable, no information of a visited site (incl. its location) could be recorded for these respondents. Therefore, these observations are excluded from any models which use site characteristics or distance between site and home location. As a consequence, the above sampling procedure means that the trip frequency variable is zero-truncated since no respondent provides information on a site which they have not visited. There is thus no observation with zero trip frequency (under current water quality conditions) in any of the count data models.

## A.2. Extraction of distance and trip duration variables

Instead of straight-line distance, the distance on the road network was extracted and used for analysis. This distance was calculated in R ( R Core Team 2020) using the osrmRoute function within the osrm package (version 3.3.1) (Giraud 2019). This function returns the travel distance ( km ) and duration (mins) using road networks. There were 66 instances of no route error returned. Additionally, there were 22 instances of where a route distance of 0 was returned but there was no error. In many cases this was because the start and visit locations were very close in straight-line distance ( $n=6<100 \mathrm{~m} ; \mathrm{n}=14<1 \mathrm{~km}$ ).

The visit coordinates were saved as a .csv file and imported into ArcGIS (version 10.6.1; ESRI Inc.). The Near function was used to identify the id number of the nearest visit location. This was imported into R and the straight-line distance between each visit location and its nearest visit location was calculated using the distVincentyEllipsoid function from the geosphere package as above (version 1.5-10) (Hijmans 2019).

## A.3. Useable samples and exclusion criteria

Two different samples were used at the different stages. For the count data models, a sample of $N=5,937$ respondents was used. To estimate total annual visitation frequencies, a sample of $N=11,443$ was used. These samples were obtained as follows. From the original dataset ( $N=18,838$ ), only respondents in 14 EU were retained ( $N=14,745$ ). In addition, observations were discarded based on a number of criteria:

- Observations for which trips were entirely for other purposes than visiting the site $(1,372)$;
- Trips which did not start at home (1,721);
- Trips with a one-way road distance of more than $1,000 \mathrm{~km}(20)$

In addition, the following criteria excluded cases with unrealistic combinations of travel mode and distance travelled, or distance travelled and visit frequency:

- Observations with a one-way road distance of more than 50 km and travel mode of either: walking (33), running/jogging (10), ferry or public boat (13) or other travel mode (9);
- Observations with a one-way road distance of more than 100 km and travel mode cycling (9);
- Observations with a one-way distance of more than 250 km and more than one visit in four weeks (66);
- Observations with a one-way distance of more than 100 km and more than four visits in four weeks (34);

Finally, one criterion was applied to discard cases claiming to make more than two visits per day over the course of the reporting period:

- Observations with a contingent trip frequency (after improvement or deterioration of water quality) of more than twice per day on average (i.e. 56 visits over four weeks) (15).
This leaves a dataset with $N=11,443$ cases to be used for calculations of total visitation numbers ("full sample"). Of this sample 2,777 cases did not make any visit to a blue space site in the preceding four weeks and for 2,729 no reliable route distance could be computed, which leaves a final sample of $N=5,937$ to be used in the count data models and visit count prediction ("travel cost sample").

Table A.1. Inclusion criteria and associated sample sizes

| Criteria | Sample size |
| :--- | ---: |
| Original survey sample | 18,838 |
| Respondents from EU countries (Bulgaria, Czech Republic, Estonia, Finland, | 14,745 |
| France, Germany, Greece, Ireland, Italy, Netherlands, Portugal, Spain, Sweden, |  |
| United Kingdom) | 13,373 |
| Trips which were entirely or partly to visit the site | 11,652 |
| Trips starting at home | 11,632 |
| Trips with a one-way road distance $\leq 1,000 \mathrm{~km}$ | 11,567 |
| Trips with a one-way road distance $\leq 50 \mathrm{~km}$ and travel mode of either: walking, | 11,558 |
| running/jogging, ferry or public boat or other travel mode | 11,492 |
| Trips with a one-way road distance $\leq 100 \mathrm{~km}$ and travel mode: cycling | 11,458 |
| Trips with a one-way road distance $\leq 250 \mathrm{~km}$ and more than one visit in four | $\mathbf{1 1 , 4 4 3}$ |
| weeks | $\mathbf{8 , 6 6 6}$ |
| Trips with a one-way road distance $\leq 100 \mathrm{~km}$ and more than four visits in four |  |
| weeks | $\mathbf{5 , 9 3 7}$ |
| Respondents reporting on average more than two visits per days over a four- |  |
| week period |  |
| Respondents with at least one visit to a blue space site in the preceding four |  |
| weeks |  |

## A.4. Country-specific descriptive statistics

Tables A. 2 to A. 15 show descriptive statistics of respondents-specific variables per country. Descriptive statistics are reported for both the full sample and the travel cost sample for each country. For variables for which they are available, respective population figures are reported as well. Note that population-level shares are with respect to each country's adult population (aged 18 and above).

Table A.2: Sample characteristics (all respondent-specific variables used in visit count modelling) - Bulgaria

## B. Construction of travel cost variable

## B.1. Overview of travel cost

The travel cost variable is constructed using the roundtrip distance between a respondent's home and the site and a per-km vehicle running cost. The calculation of the latter is detailed in Section B.2. Roundtrip distance, per-km road cost and resulting travel cost are reported per country in Table B.1.

Table B.1. Travel distance and cost

|  | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| :--- | :---: | :---: | :---: |
| Country | Roundtrip distance <br> $\mathbf{k m}$ | Road cost <br> $\boldsymbol{\ell} / \mathbf{k m}$ | Travel cost <br> $\boldsymbol{\ell} /$ trip |
| Bulgaria | 78.93 | 0.09 | 7.61 |
| Czech Republic | 32.22 | 0.05 | 2.40 |
| Estonia | 50.82 | 0.06 | 4.90 |
| Finland | 35.05 | 0.05 | 2.60 |
| France | 62.30 | 0.06 | 4.77 |
| Germany | 44.98 | 0.06 | 3.33 |
| Greece | 56.57 | 0.10 | 5.89 |
| Ireland | 41.01 | 0.06 | 2.87 |
| Italy | 62.58 | 0.08 | 5.44 |
| Netherlands | 41.10 | 0.07 | 4.20 |
| Portugal | 45.75 | 0.09 | 4.46 |
| Spain | 63.62 | 0.06 | 4.73 |
| Sweden | 34.77 | 0.04 | 2.25 |
| UK (GB) | 48.60 | 0.07 | 4.63 |
| TOTAL (EU14) | 50.14 | 0.07 | 4.35 |

## B.2. Calculation of vehicle running cost

Route distances from the respondent's home to the visited site were extracted from open street map. These distances were used to generate a road cost variable specific to the indicated travel mode.

## B.2.1. Car, van, motorbike, taxi, hire car

The calculation of country-specific per-km car running costs followed the approach in Czajkowski et al. (2015) and Bertram et al. (2020). Car running costs for a medium-sized car for petrol, oil and tyres was extracted from the Irish AA (https://www.theaa.ie/aa/motoring-advice/cost-of-motoring.aspx). Since the AA's figures assumed a petrol price of $€ 1.319$ per litre the above car running costs were adjusted for country-specific petrol prices in 2018 and finally adjusted according to purchasing power parity differences between countries. The resulting per-km car running costs per country are displayed in Table B.2.

This per-km cost is applied to respondents travelling by private car, hired car, motorbike and taxi. The cost is divided by the number of passengers in the vehicle as stated in the survey.

Table B.2. Country-specific per-km car running costs

| Country | Per-km cost <br> $(€)$ |  |
| :--- | :---: | :--- |
| Bulgaria | 0.23180 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Czech Republic | 0.17420 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Estonia | 0.18447 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Finland | 0.12383 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| France | 0.13628 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Germany | 0.13490 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Greece | 0.19404 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Ireland | 0.12837 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Italy | 0.16577 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Netherlands | 0.14826 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Portugal | 0.17382 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Spain | 0.14654 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| Sweden | 0.10550 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |
| United Kingdom | 0.14267 | Irish AA adjusted by own calculations following Czajkowski et al. (2015) |

## B.2.2. Walking, running, jogging

Road costs for these travel modes were set to zero.

## B.2.3. Bicycle

Road costs for cycling were set to $€ 0.06$ per km for all countries following Bertram and Larondelle (2017) and Brübach (2009).

## B.2.4. Bus

While in most cases bus may mean local urban bus, data on bus commuting costs were taken from EC (2016a) which provides inter-city bus fares in EU Member States. These costs are per km and per person (Table B.3).

Table B.3. Country-specific per-km costs for bus and train travel

| Country | Bus <br> Per-km cost ( $\mathbf{\xi})^{\mathbf{a}}$ | Train <br> Per-km cost ( $\mathbf{1})^{\mathbf{b}}$ |
| :--- | :---: | :---: |
| Bulgaria | 0.11 | 0.02 |
| Czech Republic | 0.07 | 0.04 |
| Estonia | 0.04 | 0.01 |
| Finland | 0.04 | 0.05 |
| France | 0.06 | 0.13 |
| Germany | 0.05 | 0.13 |
| Greece | 0.12 | 0.09 |
| Ireland | 0.04 | 0.11 |
| Italy | 0.025 | 0.07 |
| Netherlands | 0.05 | 0.12 |
| Portugal | 0.10 | 0.07 |
| Spain | 0.12 | 0.08 |
| Sweden | 0.09 | 0.05 |
| United Kingdom | 0.04 | 0.15 |
| Notes: ${ }^{\text {a }}$ from EC (2016a), ${ }^{\text {b }}$ from EC (2016b) |  |  |

## B.2.5. Train

Train costs were taken from EC (2016b). These costs are per km and per person (Table B.3).

## B.2.6. Ferry or other public boat

A per-km road cost of $€ 0.30$ is assumed.

## B.2.7. Other (e.g. horseback)

A per-km road cost of $€ 0.30$ is assumed.

## C. Computation of confidence intervals

## C.1. Confidence intervals of consumer surplus estimates

Confidence intervals of the consumer surplus estimates, $C S=-\beta_{\text {travel.cost }}{ }^{-1}$, where $\beta_{\text {travel.cost }}$ is the estimated travel cost parameter, can be computed by taking 1,000 draws from the multivariate normal distribution defined by the MPLN model's parameter vector $\boldsymbol{\beta}$ and the asymptotic variance-covariance matrix. This results in 1,000 parameter vectors, so 1,000 consumer surplus estimates can be computed. The bounds of the $95 \%$ confidence interval are the 2.5 - and 97.5 -percentiles of this empirical distribution of consumer surpluses.

## C.2. Confidence intervals of (changes in) predicted visit frequencies

Here too, 1,000 draws from the multivariate normal distribution defined by the MPLN model's parameter vector $\boldsymbol{\beta}$ and the asymptotic variance-covariance matrix are taken. For each of these draws, the resulting parameter vector is used to predict the number of visits for each water quality level according to eq. (4), and the mean is stored. The 2.5 - and 97.5 -percentile of the resulting distribution of means are reported as bounds of the $95 \%$ confidence interval. To obtain confidence intervals for the predicted changes in visit frequency the above procedure is repeated but the difference between predicted visits with improved (deteriorated) water quality and perceived current water quality is calculated for each draw.

## C.3. Confidence intervals of population-level consumer surplus figures

100,000 draws with replacement are taken from the empirical distribution of annual visit frequencies ( $N=$ 11,443 ) and the mean is stored. Then 100,000 draws from the multivariate normal distribution defined by the MPLN model's parameter vector $\boldsymbol{\beta}$ and the asymptotic variance-covariance matrix are taken. Elementwise multiplication of these vectors is used to obtain a vector of 100,000 per-annum CS values, from which the 2.5 - and 97.5 -percentile are reported as bounds of the $95 \%$ confidence interval. If the elementwise products are also multiplied with the total population one obtains the confidence interval for the population-level consumer surplus figures. These procedures can be repeated for each country surveyed.

## D. Alternative regression analysis as robustness check

## D.1. Random effects Poisson regression models

Most applications of the TC-CB method use different versions of count data models to estimate the relationship between travel cost and visit frequency. The most common models are the Poisson model and the negative binomial model. Examples of the random effects Poisson model are Whitehead et al. (2010, 2013). Applications of the negative binomial models not accounting for truncation can be found for instance in Bertram et al. (2020) and Deely et al. (2019).

Table D. 1 displays results from both models using this study's travel cost sample ( $N=5,937$ ) and the same set of covariates as in the MPLN paper reported in the paper. The estimated travel cost coefficients (B $=-0.020$ and $B=-0.023$, respectively) are significant and similar to the coefficient found in the MPLN model (Table 3). Consequently, the resulting consumer surplus estimates are similar ( $€ 49.58$ [ $95 \%$ confidence interval: 46.41-53.21] and €44.43 [41.93-47.25], respectively), albeit slightly larger than the €41.32 found by means of the MPLN model.

Table D.1. Random effects Poisson and negative binomial regression models
